

Subreport with an XML datasource

In this lab, the datasource used is an XML datasource.

The hierarchical aspect of the XML document will allow you to develop a report and subreports from the same XML document.

The *directory.xml* XML document displays people.

Each person can have different phones and different emails. We want to generate a PDF report that displays for each person, the phones and emails they own.

Develop 2 sub-reports (telephone and email) whose data source is the *directory.xml* document.

Once these two reports have been developed, work on the parent report and use the special features of JRXmlDataSource to pass the data source to the child reports.

The expected result is provided in PDF format.
